PUBLIC STATEMENTS: Report of the ACLAM Task Force on Rodent Euthanasia

Preface

The ACLAM Task Force on Rodent Euthanasia was appointed by President Lynn Anderson in 2002 in response to growing concerns and controversy regarding techniques that were commonly used for rodent euthanasia. Three issues were targeted as the focus of the report: euthanasia of fetal and neonatal rodents, the use of carbon dioxide for rodent euthanasia, and the impact of euthanasia techniques on data. The charge to the Task Force was to create a document that summarized in a scholarly and comprehensive manner all available data-based literature relevant to these topics, to assess the scientific merit of the design and conclusions of those studies, and to compile valid information into a concise and cohesive document that could serve as a resource for diplomates, other veterinarians, IACUC members, regulatory bodies, and research scientists.

The Task Force has fulfilled this charge in an exemplary manner. During 2004-2005, the ACLAM officers and Board of Directors (BOD) reviewed and critiqued two draft versions of the report, and suggestions for change were incorporated into the document presented here. In July 2005, the BOD voted to forego the usual process of distributing the document to the ACLAM membership for comment before release based on two considerations. First, the literature relevant to rodent euthanasia is continually expanding. As such, at each revision, the Task Force was compelled to incorporate new data and citations. Their consensus view was that new data would continue to emerge, and the document would require continual revision as the review process continued. Related to that, the second consideration of the BOD was that information already accumulated would be of immediate utility to the stake-holders listed above.

In lieu of a pre-publication comment period, the BOD and the Task Force instead invite all diplomates, as well as other parties, to comment via email or mail to the BOD liaison for this project, who will compile and maintain all remarks. After an interval deemed appropriate by the ACLAM President, a second Task Force will be appointed to update and modify the Report. Comments will be considered at that time.

I want to personally thank all members of the Task Force for their conscientious and comprehensive efforts in compiling this information. They have created a valuable and informative synthesis that should serve as a resource to the community for years to come.

Linda A. Toth, D.V.M., Ph.D.
ACLAM BOD Liaison to Task Force on Rodent Euthanasia

Introduction

The guidelines below were prepared by the American College of Laboratory Animal Medicine (ACLAM) to expand upon the information provided by the Report of the AVMA Panel on Euthanasia with regard to euthanasia of rodents in biomedical settings. Database searches were designed with assistance from a library scientist with advanced degrees in public health, education and research, training by AWIC and responsibility for veterinary reference materials. Keywords were selected to include all ages of rodents and all categories of rodent euthanasia identified by the 2000 AVMA Panel on Euthanasia (2). Peer reviewed publications from 1912 to 2005 were identified and evaluated prior to inclusion as references.

Professional consultation with the attending veterinarian is essential when developing plans for euthanasia and when applying these guidelines. The intent of this document is to provide guidance on rodent euthanasia performed at biomedical research facilities. Selection of the optimal euthanasia methods must be assessed on an individual basis; however, there should be consistency in the goals of all methods employed. The euthanasia of rodents should be humane, minimizing pain and fear, delivered in accordance with current regulations, ensure rapid onset of unconsciousness followed by death, and avoid risk and aversion for animals and personnel. Specific information on fetal and
neonatal euthanasia, use of CO\textsubscript{2} as an euthanasia agent, and the influence of euthanasia methods on frequently measured scientific parameters should be incorporated into the institution’s educational program for investigators.

**Euthanasia of Fetal and Neonatal Rodents**

**A. Background**

The Report of the AVMA Panel on Euthanasia (2) provides limited recommendations for the euthanasia of prenatal or neonatal animals and no specific recommendations on altricial or precocial rodents. The report states: "When ovarian hysterectomies are performed, euthanasia of feti should be accomplished as soon as possible after removal from the dam." It also states "Neonatal animals appear to be resistant to hypoxia, and because all inhalant agents ultimately cause hypoxia, neonatal animals take longer to die than adults." (2). The Panel recommends "inhalant agents not be used alone in animals less than 16 weeks old except to induce loss of consciousness, followed by the use of some other method to kill the animal." (2).

The current scientific literature provides limited evidence for the effectiveness of any of the recommended rodent euthanasia methods when performed on fetuses or neonates or the outcome on the fetuses when performed on the pregnant mother.

**B. Euthanasia of Fetuses**

By the third trimester of gestation, the neural tube has developed into a functional brain, and the likelihood that a fetus may perceive pain should be considered (12, 30). No definitive evidence indicates that prenatal rodents perceive pain, but reflexive behavior observed in fetal animals correlates with adult responses to painful stimuli (15, 55). However, low arterial oxygen concentrations may limit higher cortical processing that would mediate fetal arousal and awareness (43).

1. **Mouse, Rat, and Hamster Fetuses up to 15 Days’ and Guinea Pig Fetuses up to 35 Days’ Gestation**
   a. Neural development during this developmental stage is minimal and pain perception is considered unlikely (36, 73).
   b. Euthanasia of the mother or removal of the fetus should ensure rapid death of the fetus due to loss of blood supply and non-viability of fetuses at this stage of development (37).

2. **Mouse, Rat, and Hamster Fetuses over 15 Days’ and Guinea Pig Fetuses over 35 Days’ Gestation through Birth**
   a. The neural development during this developmental period supports the likelihood that pain may be perceived (30, 36, 73). Observations of near-term mouse and rat fetuses in vivo indicate behavioral responses to sensory stimulation (17, 65).
   b. Methods of euthanasia of fetuses
      i. Skillful injection of chemical anesthetics in sufficient quantities to ensure death.
      ii. Decapitation with sharp surgical scissors or cervical dislocation.
   c. Rapid freezing in liquid nitrogen without prior anesthesia is not considered to be humane (2).
d. When chemical fixation of the whole fetus is required, fetuses should be anesthetized prior to immersion in, or perfusion with, fixative solutions. Anesthesia may be induced by hypothermia (19, 54), or by injection with a chemical anesthetic (67).

e. Rodent fetuses are resistant to hypoxia (63). Near-term rat fetuses experiencing umbilical cord occlusion exhibited respiratory movements for up to 40 minutes after occlusion (58). Fetuses require extended exposure to inhalant anesthetics, including CO$_2$ (37).

f. When fetuses are not required for study, the method chosen for euthanasia of a pregnant mother should ensure cerebral anoxia to the fetus and minimally disturb the uterine milieu to minimize fetal arousal (37, 43). A recommended method for euthanasia of the mother is CO$_2$ exposure followed by cervical dislocation (47).

C. Euthanasia of Neonates

1. Mouse, Rat, and Hamster Neonates up to 10 Days of Age

   a. Maturation of nociceptors and the development of excitatory and inhibitory receptor systems occur during the period just prior to birth and extend into the second week of postnatal life (26, 28, 57, 70).

   b. Resistance to hypoxia results in a prolonged time to unconsciousness when CO$_2$ inhalation is used as a euthanasia agent (2, 37, 47). The duration of exposure to carbon dioxide varies with the age of the neonate. Inbred and outbred neonatal mice less than 7 days of age may differ in susceptibility to CO$_2$, requiring exposures as long as 50 minutes to ensure euthanasia (55).

   c. When using CO$_2$ for euthanasia, death must be verified prior to disposal of the carcass (51).

   d. Other methods for the euthanasia of neonatal mice and rats

      i. Injection of chemical anesthetics in sufficient quantities to ensure death.

      ii. Decapitation.

      iii. Cervical dislocation.

   e. Immersion in liquid nitrogen should be performed only if preceded by anesthesia. Anesthesia should precede immersion in, or perfusion with, chemical fixatives.

   f. Anesthesia in neonatal rodents may be induced by inhalant or injectable anesthetics. Prolonged exposure to inhalant anesthetics (e.g., halothane or isoflurane) may be necessary. Alternatively, hypothermia may be used to induce anesthesia in pups 6 days of age or less (19, 54). The attending veterinarian should be consulted for appropriate techniques and drug dosages.

2. Guinea Pig Neonates

   Follow guidelines for adults (2).

3. Mouse, Rat, and Hamster Neonates over 10 Days of Age

   Follow guidelines for adults (2).
The Use of CO₂ for Euthanasia of Rodents

A. Background

Carbon dioxide (CO₂) is a frequently used euthanasia agent for small laboratory animals due to its rapid onset of action, safety, low cost, and ready availability. It most commonly is used to euthanize rats and mice, which constitute the majority of animals used in biomedical research and are the focus of most studies on the use of CO₂ euthanasia. The same delivery system and equipment can be used to euthanize either single animals or groups of animals with CO₂. Despite its widespread use, euthanasia methods using CO₂ are not standardized. The current peer reviewed literature does not establish consistent requirements for CO₂ euthanasia and or even provide a clear definition of what constitutes a humane death. The acceptability of CO₂ for euthanasia under various conditions, and for various species and ages of animals, must continue to be re-evaluated as new data become available.

B. General Considerations

Changes in the animal’s environment or novel conditions should be minimized to the degree that is practical. Rodents are sensitive to their environment and to handling (42, 59, 62). Removal from the home cage (14), regrouping with other animals (44), introduction to new sites and odors (11), and transport and placement into the euthanasia chamber can alter physiologic and metabolic parameters and possibly cause stress. Researchers and animal care staff should seek methods that minimize the stress experienced by rodents that undergo CO₂ euthanasia. Transporting animals and performing euthanasia in the home cages, using carts that are quiet, roll freely, and do not jostle cages or occupants, and minimizing regrouping to prevent social aggression are simple approaches to lessening potentially stressful conditions.

C. Euthanasia Chambers

1. Euthanasia chambers should be kept clean and free of debris and excreta.
2. The euthanasia chamber should be large enough to permit each animal to stand on the floor of the chamber with all four feet and have sufficient space to turn around and perform normal postural adjustments.

D. CO₂ Gas Delivery Systems

1. Sufficient carbon dioxide must be introduced into the chamber to totally displace the residual air by both mixing and dilution. Ideally, the inlet for delivery of CO₂ and any diffusion devices in the euthanasia chamber should provide a predictable and controllable elevation in CO₂ concentration.
2. Excess gas must be allowed to escape from the chamber in a way that allows a gradual increase in the concentration of CO₂ at the floor of the container that holds the animal. Escape of the gas mixture through a port, or other opening at the top of the chamber, must occur in a controlled manner that neither pressurizes the chamber nor permits reflux of room air into the chamber.
3. Carbon dioxide should be delivered using a two-stage regulator, with the second stage capable of adjustable fixed flow rates.
4. Large chambers designed for euthanasia of groups of animals may require multiple inlets, or diffusion devices, to facilitate different configurations for CO₂ introduction.
5. The use of heated valves assures constant delivery of gas to the chamber by avoiding the formation of dry ice within valves and regulating systems when units are used for prolonged or repeated periods.
6. The filling rate of the chamber should be based upon the time required to rapidly and successfully render the animals unconscious. This may differ from the amount of time required to achieve a lethal concentration of CO₂. Each type of chamber will have a different CO₂ filling profile based upon gas flow rate, gas dispersion characteristics, gas inlet locations and chamber dimensions.

7. Chambers should be filled with CO₂ at a flow rate that balances the time to unconsciousness with such associated aversive stimuli as noise or high velocity air movement.

8. A fill rate of 20% of the chamber volume per minute has been recommended as an appropriate means to achieve a lethal concentration (31). However, animals should be closely observed during the filling process, as individual systems may require adjustment to achieve the desired effect (2).

E. Pre-filling vs Not Pre-filling the Euthanasia Chamber

1. Because inspiration of high concentrations of CO₂ is both aversive and painful (9, 19, 40), a recommended procedure is to place animals into a chamber that contains room air and then to gradually introduce CO₂.

2. The use of CO₂/oxygen gas mixtures and slow fill rates prolong the time to unconsciousness and death and may increase distress for the animals. There is no conclusive evidence that adding pure oxygen to carbon dioxide makes this procedure less stressful to animals (13, 20, 29, 39). A fill rate of 20% of the chamber volume per minute with carbon dioxide, added to existing room air in the chamber should be appropriate to achieve a balanced gas mixture to fulfill the objective of rapid unconsciousness with minimal distress to the animals.

F. Cautionary Information

1. Animal carcasses should not be exposed to room air until death has ensued with high certainty, as the anesthetic effects of CO₂ can be quickly reversed in the presence of oxygen.

2. Individual rodents may become apneic at certain concentrations of CO₂, giving the false impression that death has occurred (9).

3. Confirmation of death should be based not on a single sign, such as cessation of breathing, but on multiple signs, such as physical examination, exposure to room air (under observation), or adjunctive methods of euthanasia (decapitation, cervical dislocation, pneumothorax).

4. Euthanasia apparatus should be regularly evaluated to ensure proper functionality sufficient to achieve 100% euthanasia of all animals. Failure to function correctly may result in the need to re-expose an animal to carbon dioxide to achieve euthanasia. Re-exposure should take place before the animal regains consciousness.

The Influence of Euthanasia Method on Frequently Measured Scientific Parameters

A. Background

The method of euthanasia can influence the validity of scientific results. *The Guide for the Care and Use of Laboratory Animals* indicates the appropriate euthanasia method depends on many criteria, including compatibility with research objectives (48). It further states, “The selection of specific agents and methods for euthanasia will depend on the species involved and the objectives of the protocol.” (48). Euthanasia, as a process, separates the presentation of new variables, treatments or environmental changes to the living system from the
terminal collection of tissues and blood for additional study or analysis. In itself, the euthanasia method can alter physiologic parameters and responses.

The effects of handling during the euthanasia process, proficiency of personnel performing euthanasia, and mechanical efficiency of equipment can introduce variables that influence the welfare of the animal and the interpretation of the data. Such factors as the species and age of animal, measurements to be assessed, sampling sites, and time of tissue collection, additionally influence sample analysis and histology.

The existing literature should be assessed for general information. However, the specific impact of any euthanasia method on scientific results may require case-by-case validation.

The euthanasia technique should minimally impact the welfare of the animal and the handler and must support collection of reproducible scientific data.

The researcher must evaluate the scientific consequences of the chosen method of euthanasia.
### B. Biological Effects of Euthanasia Techniques

| Cervical dislocation and halothane (32) | Normal mitogen induced lymphocyte proliferation  
Decreased CTL response |
|-----------------------------------------|--------------------------------------------------|
| CO₂ and cervical dislocation (32)      | Normal mitogen induced lymphocyte proliferation  
Decreased CTL response |
| CO₂ and decapitation (4, 23, 66)       | Normal LH, FSH, prolactin, corticosterone  
Activity of cholinergic markers identical to decapitation only  
Altered GABA₆ receptor function |
| Focused beam microwave irradiation (FBMI)³ (41, 45) | Best technique for measuring adenosine levels  
Decreased brain amino acids: alanine, GABA₆  
ethanolamine, NH₃, valine, leucine, isoleucine,  
tyrosine, phenylalanine, glycine, aspartate  
Increased levels of reduced glutathione, glutamate  
Due to rapid inactivation of metabolizing enzyme |
| CO₂ (8, 52, 69)                        | 100% CO₂ : decreased mean corpuscular hemoglobin  
(NP)³ Increased total leukocytes and granulocytes  
(P)⁵ Decreased liver glycogen, pyruvate, ATP  
No change in platelet counts  
CO₂ causes acidosis that affects RBC parameters |
| CO₂ or CO₂/O₂ (8, 27, 34, 46, 52, 69)  | Increased hematocrit, mean corpuscular volume  
No change in serum norepinephrine, dopamine,  
serotonin, corticosterone⁶  
Decreased serum creatine kinase, aspartate  
aminotransferase  
Significant decreased liver glycogen stores  
Increased serum glucose  
Decreased activity of enzymes regulating branched  
chain amino acid degradation  
Decreased mean erythrocyte hemoglobin, mean  
corpuscular hemoglobin concentration  
CO₂ causes acidosis that produces stimulation of enzymes of the glycolytic pathway |
| 70% CO₂/30% O₂ vs 100% (Pre-charged) (52) | Decreased number of circulating CD3⁺ and CD8⁺ T cells  
Increase in CD10⁺ B cells in circulation |  
| 70% CO₂/30% O₂ vs 100% (Not pre-charged) (52) | Increased number of circulating CD3⁺, CD4⁺, and CD8⁺ T cells | NOTE: 100% CO₂ (Non-precharged and pre-charged) had overall greater T-cell counts than 70% CO₂/30% O₂ euthanized animals |  
| Isoflurane (8) | No change in liver glycogen |

NOTE: DC (decapitation), CD (cervical dislocation), CO₂, Intracardiac pentobarbital more suitable for histology of abdominal viscera

1 preferred for isolated beating heart preparations
2 preferred method (by IV route) for collection of tissues, including liver, for cyclic AMP assay
3 FBMI minimizes post-mortem neurochemical changes. Leaves brain landmarks intact
4 (NP) = Not precharged
5 (P) = Precharged
6 exposure to CO₂ prior to decapitation
7 reported to release massive sympathetic response with ↑ catecholamines from adrenal gland
8 produces changes in hemodynamics – capillary contraction, followed by dilation of capillaries and veins (except lung vessels); depresses cerebral cortex, stimulates chemoreceptors; extravasation to alveoli: Not seen in all rodent species
ADDITIONAL FACTORS THAT INFLUENCE THE OUTCOME OF EUTHANASIA:  (6, 7, 18, 22, 38, 56)

1. Handling: May cause sympathoadrenal discharge, which affects plasma glucose, progesterone plasma catecholamines. Habituating the animals to handling may mitigate this effect.
2. Environmental stimuli (e.g., noise) can increase plasma corticosterone concentrations.
3. Sequence: The order of euthanasia for rats housed in pairs produced significant differences in plasma tryptophan and unesterified fatty acids, plasma corticosterone, plasma protein lactate levels, substance P, cholecystokinin, somatostatin.
